Abstract

This paper first presents a taxonomy of detection language and then a methodology for estimating detection languages in term of their expressive ability, succinctness and detection complexity is developed.

1. Introduction

Many detection languages have been proposed to specify attack signatures in order to detect misuses. An interesting question thus arises: How does one evaluate and compare different formalisms of attack signatures? Besides the practical aspect of this question with respect to choosing the “best” formalism for a given application, environment, and resource constraints, a methodology for comparing and evaluating attack signature representation methods may lead to useful introspection, new insights, and to the discovery of better approaches.

This paper first introduces a kind of taxonomy to classify detection languages in section 2. Then section 3 formally defines three metrics: expressibility, succinctness and detection complexity and compares various formalisms of attacks by these metrics.

2. The Classification of Detection Languages

First, let us explain two operators. Operator \circ concatenates two sequences of filter. Operator \bullet means the arbitrary concatenation of two sequences of filter, regardless of the order. For example, $\omega_1 \bullet \omega_2 = \{ 'ABCD', 'ACBD', 'ACDB', 'CABD', 'CADB', 'CDBA' \}$. Let S_1, S_2, S be arbitrary scenarios, where S is combined by S_1 and S_2 :

Definition 1:

then $(S = S_1 \text{ then } S_2): S = \{ \omega_1 \circ \omega_2: \omega_1 \in S_1, \omega_2 \in S_2 \};$

or $(S = S_1 \text{ or } S_2): S = S_1 \cup S_2;$

and $(S = S_1 \text{ and } S_2): S = \{ \omega_1 \bullet \omega_2: \omega_1 \in S_1, \omega_2 \in S_2 \}.$

Definition 2:

γ Relation: Let M' be the set of detection languages, $\gamma = \{ (M_1, M_2): M_1, M_2 \in M' \text{ and } \forall x: x \in \{ \text{then, and, or} \}, "M_1 \text{ supports } x" \Leftrightarrow "M_2 \text{ supports } x" \}$

Obviously, γ is reflective, symmetrical, and transitive.

Definition 3:

Classification μ : μ is a classification on M' based on γ relation.

$\mu = \{ \{ \{ \} \}, \{ \{ \text{then} \} \}, \{ \{ \text{and} \} \}, \{ \{ \text{or} \} \}, \{ \{ \text{then}, \text{and} \} \}, \{ \{ \text{then}, \text{or} \} \}, \{ \{ \text{and}, \text{or} \} \}, \{ \{ \text{then}, \text{and}, \text{or} \} \} \}$, where $\forall x: x \subseteq \{ \text{then}, \text{and}, \text{or} \}, [x] = \{ M \mid M \in M' \text{ and } M \text{ supports and only supports the combination ways in } x \}$. For convenience, we omit the set notation of x in $[x]$, that is, $\{ \{ \text{then}, \text{or} \} \}$ is written as $[\text{then}, \text{or}]$. Colored Petri-net[1] is an element of $[\text{then}, \text{or}, \text{and}]$, however

statl[2] belongs to [then,or]

The classification μ is based on the syntax elements of detection languages, which guarantees non-ambiguity and repeatability. Moreover, μ is mutual exclusive and complete, because it is the classification based on equivalence relation.

3. Some Metrics of Estimating Detection Languages

As any attack Scenario can be described by enumerating all filter sequences, which is the most verbose form of description, it becomes a baseline for estimating succinctness. The signature base generated by enumeration is thus called the baseline of signature base \mathcal{R} , written as $KL(\mathcal{R})$.

Let M' be the set of detection language, \mathcal{R}' be the set of signature base \mathcal{R} , $DL(x)$ returns signature base x 's detection language.

Definition 4: Relative Expressibility

The Equivalence of Expressibility $LG=$:

$$LG= = \{(A, B): A, B \in M' \wedge \forall x(x \in \mathcal{R}' \wedge DL(x)=A \rightarrow \exists y(y \in \mathcal{R}' \wedge DL(y)=B \wedge Kl(x)=Kl(y))) \wedge \forall y(y \in \mathcal{R}' \wedge DL(y)=B \rightarrow \exists x(x \in \mathcal{R}' \wedge DL(x)=A \wedge Kl(x)=Kl(y)))\}$$

Similarly, we can define $LG<$ and $LG>$.

Observation 1: 'then' is the prerequisite operator in describing multiphase scenarios. The expressibility will not be enhanced even if more ways of combination are supported.

Conclusion 1: [] $LG<$ [then] $LG=$ [then,or] $LG=$ [then,and] $LG=$ [then,or,and]

Definition 5: Succinctness

$f: M' \rightarrow N$ is a function from the set of detection languages to natural number. $\forall \mathcal{R}: DL(\mathcal{R})=M$, $f(M)$ is defined as the maximum growth rate of size when \mathcal{R} is transformed into $Baseline(\mathcal{R})$. The greater $f(M)$ is, the more succinct M is.

Observation 2: Under the condition that 'then' has been supported, the succinctness of expression will be

enhanced in polynomial if 'or' is supported as a plus, and in exponential if 'and' is supported as a plus.

Conclusion 2:

$$[then] < [then,or] < [then,and] < [then,or,and]$$

Definition 6: Detection Complexity

$\mathfrak{Z}: M' \rightarrow N$ is a function from the set of M to the set of natural number. $\forall \mathcal{R}: DL(\mathcal{R})=M$, $\mathfrak{Z}(M)$ is the maximum growth rate of reasoning time when \mathcal{R} is transformed into $Baseline(\mathcal{R})$. $\mathfrak{Z}(M)$ is a function of the size of signature base. The greater $\mathfrak{Z}(M)$ is, the more stronger M 's detection ability is.

Observation 3: Under the condition that 'then' operator has been supported, the detection complexity will be increased in polynomial if 'or' operator is supported as a plus, and in exponential if 'and' operator is supported as a plus.

Conclusion 3: [then] < [then,or] < [then,and] < [then,or,then]

4. Conclusion

From the perspective of expressive ability, detection languages can be categorized into two classes, that is, unit-event languages and multiphase languages. The multiphase languages have the same expressive ability, though they are of different forms. The combination method 'then' is the prerequisite for describing multiphase attack. The combination method 'and' and 'or' can enhance the succinctness and detection complexity of languages
